Harmony and form in Brazilian Choro: A corpus-driven approach to musical style analysis

Fabian C. Moss [a], Willian Fernandes Souza [b] and Martin Rohrmeier [a]

[a]Digital and Cognitive Musicology Lab, Digital Humanities Institute, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland; [b]Cognição Musical e Processos Criativos, Programa de Pós-Graduação em Música, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

ABSTRACT

This corpus study constitutes the first quantitative style analysis of Choro, a primarily instrumental music genre that emerged in Brazil at the end of the 19th century. We evaluate its description in a recent comprehensive textbook by transcribing the chord symbols and formal structure of the 295 representative pieces in the *Choro Songbook*. Our approach uncovers central stylistic traits of this musical idiom on empirical grounds. It thus advances data-driven musical style analysis by studying both harmony and form in a musical genre that lies outside the traditional canon.

1. Introduction

A continuously growing body of corpus studies in the field of computational music analysis aims at investigating centuries-old music-theoretical questions with modern data-driven approaches.[1] This leads not only to refinements of the questions asked and advances in the applied methodologies, but also to the creation of symbolic datasets that facilitate style analysis. Existing resources cover a diversity of musical genres, encodings, formats, and methodologies. Many datasets concentrate on melody (Brinkman & Huron, 2018; Ferola et al., 2009; Huron, 1996; Pearce & Wiggins, 2004; Von Hippel & Huron, 2000), or harmony (Albrecht & Shanahan, 2012; Burgoyne et al., 2013; Hedges & Rohrmeier, 2011; Moss et al., 2019; Rohrmeier & Cross, 2008; Temperley & de Clercq, 2013; Tymoczko, 2003; White & Quinn, 2016), but rarely consider aspects of formal structure (for an exception see Sears et al., 2017) in order to describe, infer, or predict idiosyncrasies and prototypical patterns of a certain style, genre, or composer.

Although augmenting musical style analysis by applying statistical methods as well as concepts and measures from information theory has long been acknowledged by musicologists (Manzara et al., 1992; Meyer, 1957; Pearce & Wiggins, 2004; Weiß et al., 2018; Youngblood, 1958), the computational analysis of symbolic corpora has faced several difficulties due to the diversity of analytical methods (Basili et al., 2004; Brackett, 2016; Fabbri, 2014; McKay & Fujinaga, 2006) and the lack of standardised encoding and annotation formats (Neuwirth et al., 2018; Oramas et al., 2018).

In the words of Leonard Meyer, the goal of style analysis is 'to describe the patternings replicated in some group of works, to discover and formulate the rules and strategies that are the basis for such patternings, and to explain in the light of these constraints how the characteristics described are related to one another' (Meyer, 1989, p. 38). In this spirit, the present study provides an empirically-grounded style analysis of the musical genre of Choro, a primarily instrumental Brazilian music genre. Choro is a musical practice that lies outside of canonical datasets in music information retrieval (Panteli et al., 2018; Savage, forthcoming) on classical music, e.g. Bach, Haydn, Mozart, Beethoven (Jacoby et al., 2015; Moss et al., 2019; Rohrmeier & Cross, 2008; Sears et al., 2017), and popular music, e.g. Jazz, Beatles, Charts (Broze & Shanahan, 2013; Gauvin, 2015; Harte, 2010), and has thus not been extensively studied empirically so far. We take as our starting point the recent and comprehensive theoretical account *A estrutura do Choro* (Almada, 2006) and evaluate the descriptions therein against transcriptions of a collection of representative Choro pieces from the *Choro Songbook* (Chediak, 2009, 2011a, 2011b).

Our analyses consider the chord symbols and the formal structure of Choro pieces with computational

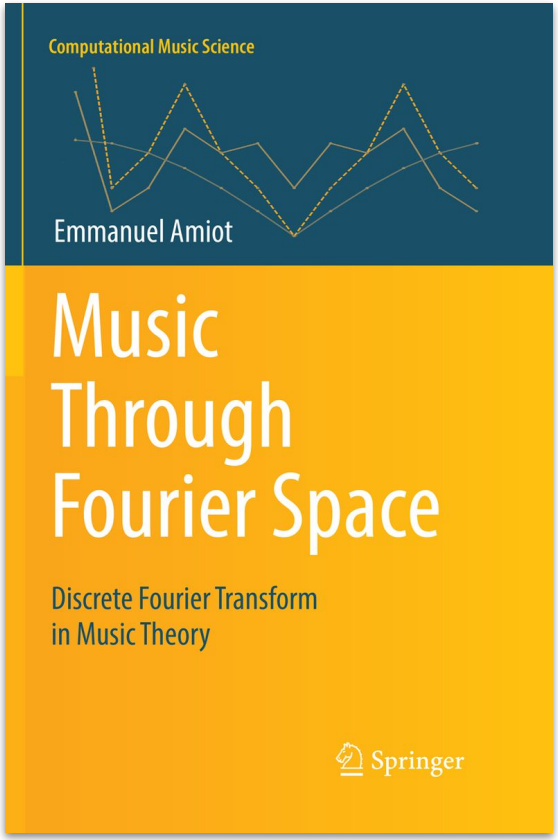
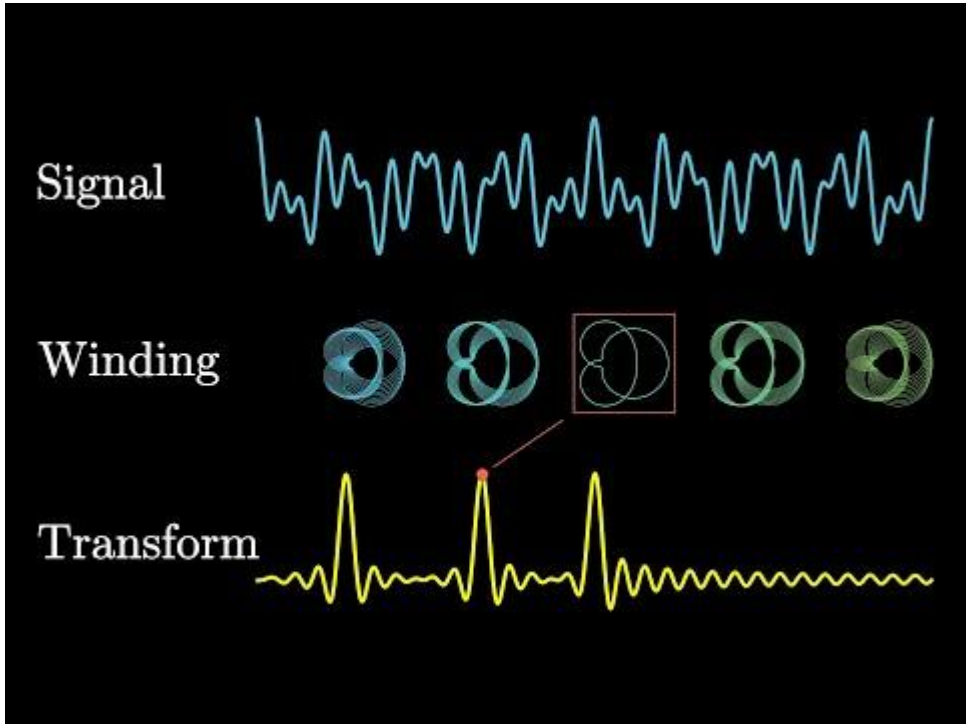
Music Analysis and the DFT

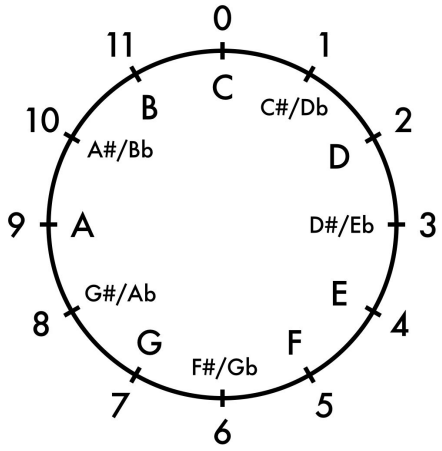
Music Theory and the Discrete Fourier Transform

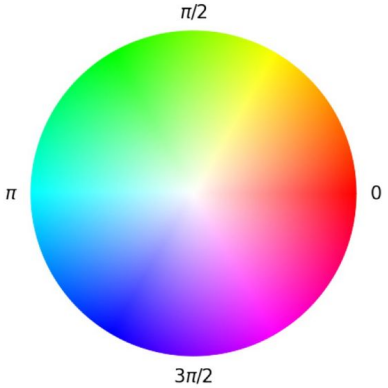




https://www.youtube.com/watch?v=spUNpyF58BY

Discrete Fourier Transform (DFT)





Def.: A *pitch-class vector* $x = P(s, w)$ contains counts all pitch classes for a segment starting at s with width w.

Definition 3.1 (Discrete Fourier Transform). The *discrete Fourier transform* (DFT) of any pitch-class vector x (i.e., any choice of $x = P(s, w)$) corresponds to the mapping

$$F\colon \mathbb{R}^{12}_{\geq 0} \to \mathbb{C}^{12}, \qquad F(x)[k] = \sum_{j=0}^{11} x[j] e^{i2\pi j \frac{k}{12}},$$

and $F(x)[k]$ is called the k-th *Fourier coefficient* of x.

Def.: Dividing a *pitch-class vector* by its sum returns a pitch-class distribution:

$$\tilde{P}(s, a) = P(s, a) / \textstyle\sum_j P(s, a)[j]$$

Wavescapes: A visual hierarchical analysis of tonality using the discrete Fourier transform

Cédric Viaccoz, Daniel Harasim, Fabian C. Moss and Martin Rohrmeier
Digital and Cognitive Musicology Lab, École Polytechnique Fédérale de Lausanne, Switzerland

Abstract
Many structural aspects of music, such as tonality, can be expressed using hierarchical representations. In music analysis, so-called keyscapes can be used to map a key estimate (e.g., C major, F minor) to each subsection of a piece of music, thus providing an intuitive visual representation of its tonality, in particular of the hierarchical organization of local and global keys. However, that approach is limited in that the mapping relies on assumptions that are specific to common-practice tonality, such as the existence of 24 major and minor keys. This limitation can be circumvented by applying the discrete Fourier transform (DFT) to the tonal space. The DFT does not rely on style-specific theoretical assumptions but only presupposes an encoding of the music as pitch classes in 12-tone equal temperament. We introduce *wavescapes*, a novel visualization method for tonal hierarchies that combines the visual representation of keyscapes with music analysis based on the DFT. Since wavescapes produce visual analyses deterministically, a number of potential subjective biases are removed. By concentrating on one or more Fourier coefficients, the role of the analyst is thus focused on the interpretation and contextualization of the results. We illustrate the usefulness of this method for computational music theory by analyzing eight compositions from different historical epochs and composers (Josquin, Bach, Liszt, Chopin, Scriabin, Webern, Coltrane, Ligeti) in terms of the phase and magnitude of several Fourier coefficients. We also provide a Python library that allows such visualizations to be easily generated for any piece of music for which a symbolic score or audio recording is available.

Keywords
Discrete Fourier transform, music analysis, keyscapes, tonal hierarchy, visualization

Many domains of human cognition, such as music, language and action planning, exhibit hierarchical structure (Arbib, 2013; Rebuschat et al., 2012). In the case of music, several structural features are organized hierarchically, for instance formal arrangement, rhythm, melody

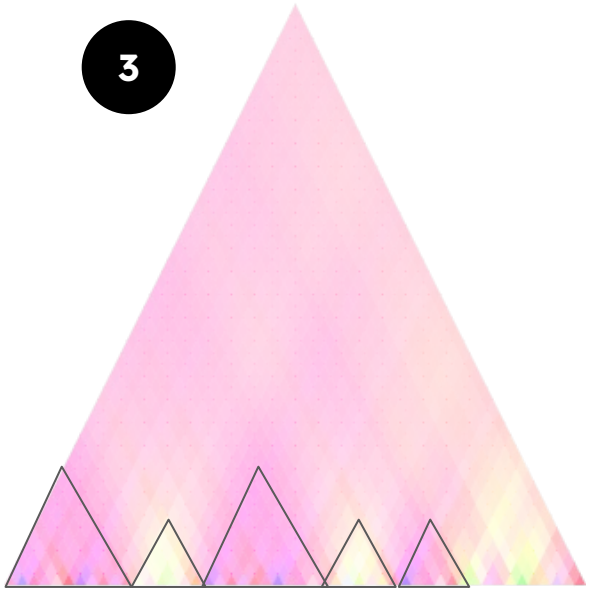
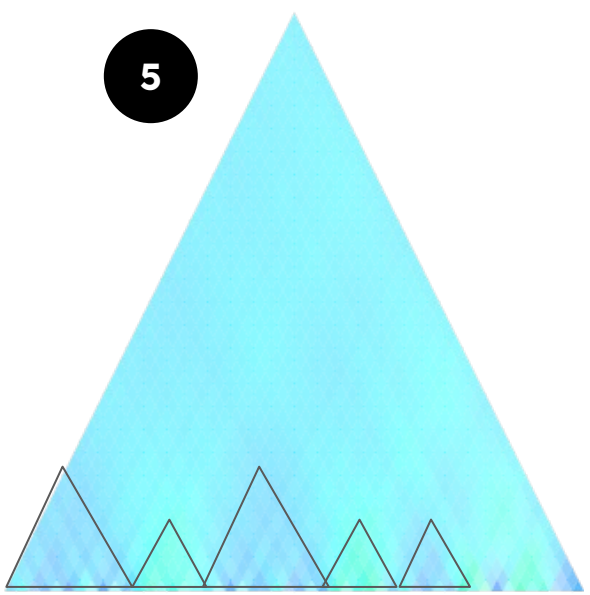
“dyadicity”



“triadicity”



“diatonicity”

Let’s try it out

- Download your favorite song as a MIDI file (Google it)
- Got to https://dcmlab.github.io/midiVERTO
- Upload the file and wait until the wavescapes have loaded
- Try to understand the plots, find interesting areas
- Modify the parameters and see how the visualizations change
- Which aspects of the piece’s tonality can you find in the wavescapes or phantom curves?

Many open questions

- How to deal with diversity of sources?
- How to include sheet music and performance recordings?
- How to deal with {melody, rhythm, harmony, …} together?
- (How) can we relate Choro to historical precursors?
- …
- → How can technology and digital methods help us to study Choro?

Thank you for your attention!
